Faster & Much Faster

The remarkable progress made in the area of rough milling in the 1990's saw the introduction of fast feed milling (FF), also referred to as high feed milling (HFM). These highly efficient methodologies overturned established views and brought radical new ideas to the field.

Rather than use the traditional high metal removal technique – milling with considerable depths and widths of cut – users of the new approach continued to machine with similar width of cuts, although they used a much smaller depth of cut and applied much faster speeds with substantially increased feed per tooth.

Milling with a large axial depth of cut (DOC) requires the kind of cutting force provided by high-power machine tools, whereas FF roughing with shallow DOC needs a lot less

machine power, although the cutting tool should run fast. Therefore, light-duty machines featuring axis drives with sufficient velocity are sufficient for FF milling.

Energy saving shallow-cut “fast” technology provides an excellent alternative to power consuming deep-cut methods. Impressive high metal removal rates (MRR) at reduced power input is not the only advantage of the strategy-FF milling delivers two additional benefits.

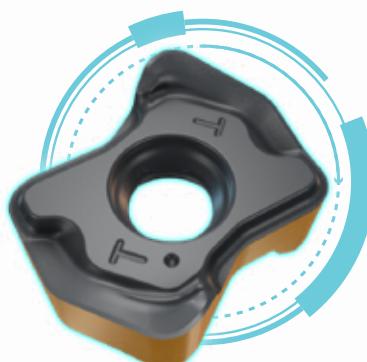

Shallow DOC enables contours to be produced that are very close to the final required shape of a machined surface, reducing or even eliminating semi-finish passes. In addition, the small cutting edge angles of FF milling cutters allows considerable increases in feeds and speeds per tooth (f_z) due to the effect of chip thinning.

HIGH FEED MILLING

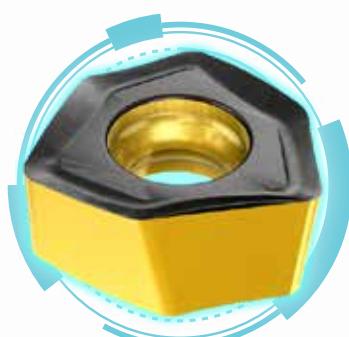

This advantageous geometry minimizes the radial effect of the cutting force and maximizes its axial influence, resulting in forces that act towards the spindle axis, i.e. the direction of maximum machine tool rigidity. The result - improved milling stability, reduced vibrations, prolonged tool life, reduced power consumption and increased productivity.

Although FF strategies began in the area of indexable milling, they soon extended to solid carbide endmills and became popular in the global die and mold making industry due to their efficiency when machining complicated shapes and cavities, especially of small sizes. Due to diverse and frequent changing working programs, fast low-power machining centers and advanced CAD/CAM software, die and mold producers quickly saw the value of the new strategy.

Although carbide endmills were the most commonly used cutting tools, FF milling cutters of relatively small diameters were also very popular prior to the introduction of the new strategy. Subsequently, the FF approach came to fast feed facing ("triple F") and opened the way to the development of various indexable face milling cutters. Now, given the amount of face milling that takes place in this major global area, general engineering is the main consumer of these tools.

Fast Feed Milling Cutters

These milling cutters are a key factor in fast feed milling techniques. The cutter geometry, designed for efficient chip thinning, needs to ensure correct distribution of the cutting force components. There are two principal geometrical approaches. The first design requires the cutting edge of an FF milling cutter to be an arc of a great circle.

Another concept is based on using one or two straight edges that are chords of the arc. In both cases, the small cutting edge angle (usually 9-17°) meets the requirements of chip thinning and total cutting force. Ensuring the geometry of solid carbide fast feed endmills and replaceable milling heads demands the specific shape of a cutting edge, while in indexable milling it may be provided by the appropriate location of an insert of even a simple profile.

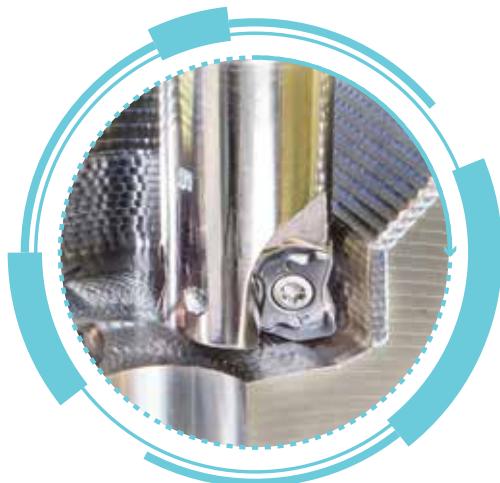

Although the introduction of innovative carbide grades and advances in the form of rake faces has further improved progress in FF milling cutters, the essential element of fast feed milling – geometry – remains constant.

Chip thinning due to the cutting edge of a FF milling cutter is the arc of a great circle (or the chords that approximate the arc), making the cutter a toroidal tool. The latter being rotated around their axis produces a torus or ring-shape. A typical representation of a toroidal tool is a milling cutter carrying round (button) inserts.

The cutting edge angle of the cutter is not a constant value but varies depending on the axial depth of cut from 0 to 90°. Decreasing depth reduces the cutting edge angle resulting in thinner chips. The programmed feed per tooth for a cutter with round inserts relates to the maximal

NAN₃FEED

HIGH FEED MILLING

TANG4FEED
HI-FEED MILLING

MICRO3FEED
MF 300 ENDMILL

diameter of the cutter, i.e. to the maximal depth of cut (it is equal to the insert radius) and the maximal cutting edge angle.

But if the cutter mills under the maximal depth, the chip is thinner; and therefore the programmed feed should be increased correspondingly in order to produce the chips of required thickness. The same situation is observed in ball-nose milling tools, and explains why FF cutters run so fast.

ISCAR offers a wide variety of fast feed milling families that represent different classes of indexable tools, solid carbide endmills and solid carbide interchangeable heads with Multi-Master threaded connections. This guide is intended for quick selection of the most suitable fast milling tool for a specific application depending on the material to be machined, the type of operation (like milling plane, pocket etc.), machining stock, and others.

| | Cast iron | Hardened | 41 | | 45-55 | | | | | | | | | 45-65 |

- For machining in unstable conditions (long overhang, poor toolholing etc.) the recommended cutting data should be reduced by 20-30%
- Recommended cutting speeds, which relate to the most suitable grades, are emphasized by **bold**

Recommendations for Machining Methods

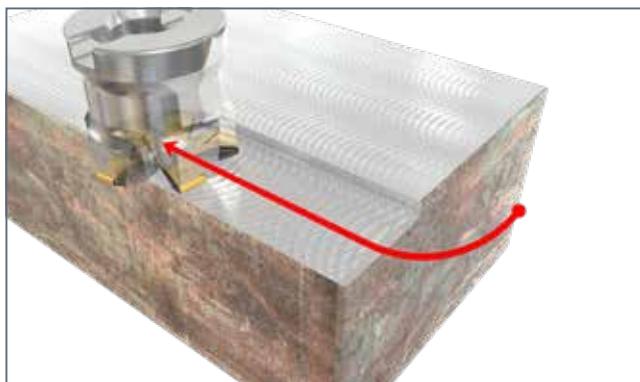

Face Milling Including Milling Next to Square Shoulder

- It is recommended that a width of cut be no more than diameter DC in order to prevent tooth overloading, because of excess machining allowance in cusps produced on the further passes after stepdown
- Down (climb) milling is preferable

Cutting into material

In milling, an approach cut by arc ("rolling in") is preferable. When a milling cutter enters a machined material by arc, chip thickness (and therefore, loading the cutting edge) grows to a maximum value progressively and then gradually diminishes to zero. It significantly contributes to machining stability, improves tool life, and reduces vibrations.

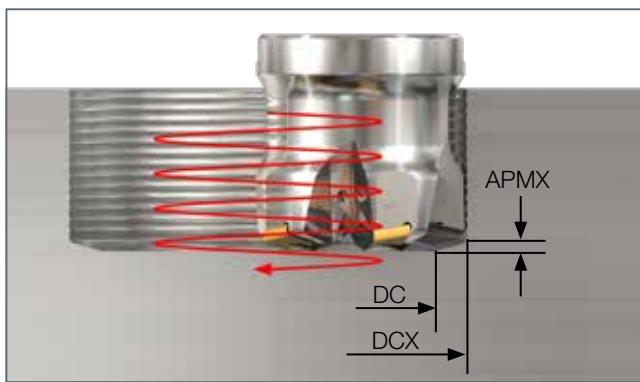

Milling Hole of Diameter D by Helical Interpolation

Maximum and minimum hole diameters D_{max} and D_{min} correspondingly:

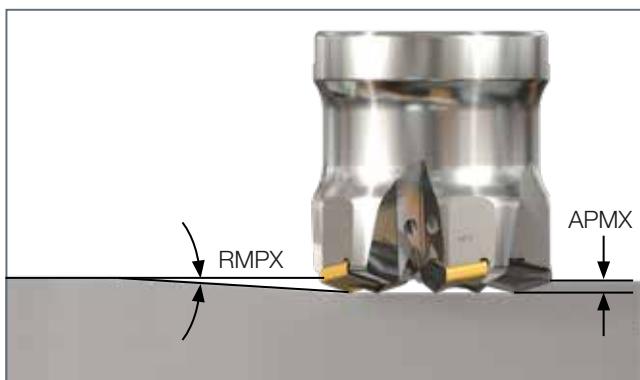

$$D_{max} = 2 \times DCX - 1, D_{min} = DCX + DC$$

- Down (climb) milling is recommended, however if chip evacuation is problematic, up (conventional) milling may give better results
- Helical pitch should not exceed maximum depth of cut $APMX$
- Helix angle should not exceed maximum ramping angle $RMPX$
- It is recommended to reduce feed per tooth f_z by 30-40%

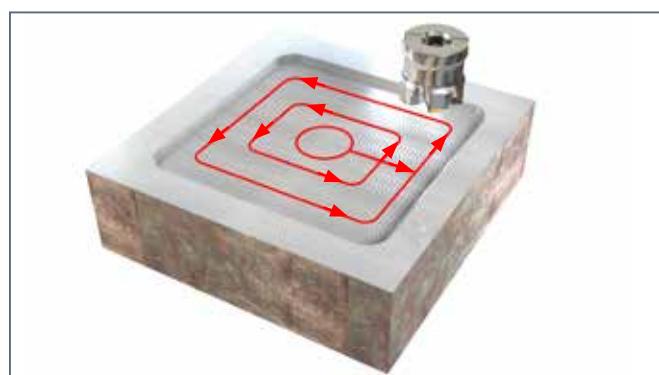

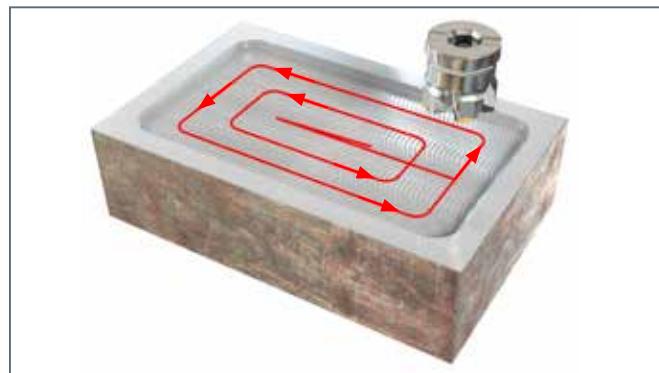

Milling by Ramping Down

- Depth of ramping per pass should not exceed maximum depth of cut $APMX$
- Ramping angle shall not exceed maximum ramping angle $RMPX$
- Down (climb) milling is preferable
- It is recommended to reduce feed per tooth f_z by 30-40%

Pocket Milling

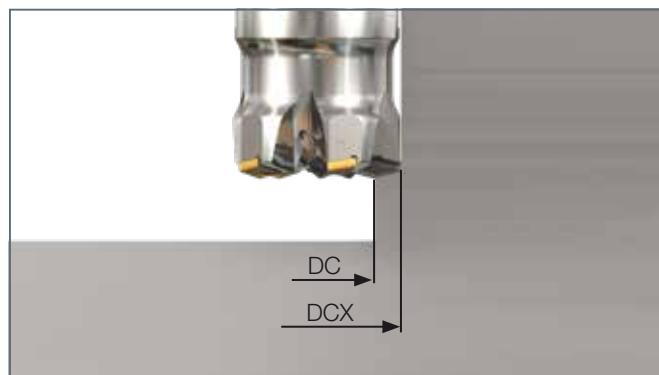

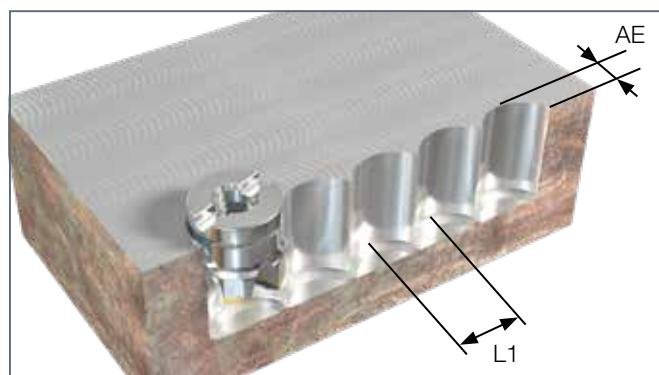

- In pocket milling, machining from center to outside contour is preferable
- In ramping down by line or helix, depth of ramping per pass should not exceed maximum depth of cut APMX and ramping angle should not exceed maximum ramping angle RMPX
- In ramping down passes, it is recommended to reduce feed per tooth fz by 30-40%

Side Plunge Milling

- The relationship between L1max and ae is given by the following formulas:
$$ae_{max} = (DCx - DC)/2$$

$$L1_{max} = 2 \times \sqrt{DCx \cdot ae - ae^2}$$
- Plunge milling is an effective and economical method for machining deep cavities, walls, slots and shapes
- Plunge milling can provide a good solution for unstable and low-power milling machine tools

FAST FEED MILLING
